The synthesis of phosphorus- and arsenic-bearing sodium (potassium) feldspars have been carried out in hydrothermal conditions at T=400–600°C, P=1.5 kbar. The microprobe analysis of synthetic P-, As-bearing feldspars was carried out. Cell parameters were calculated from X-ray data. It is shown a good correlation between cell parameters of different feldspars and average means of radius of tetrahedral cations.

Key words: synthesis, feldspars, cell parameters, solid solutopns
